**PERCEPTION OF HEALTH PROFESSIONALS ABOUT EARLY INTERVENTION SERVICES**

Iara Vieira Ramos¹, Aline Martins de Toledo¹, Andrea Baraldi Cunha²

¹ Program in Rehabilitation Sciences at the University of Brasília (UnB), Ceilândia/Distrito Federal, Brazil.
² University of Nebraska Medical Center, Department of Physical Therapy – Omaha (NE), United State of America

**Background:** Family-Centered Care is an approach that has been widely used in early intervention (EI) programs. This approach focuses on the child and their family as the central role in all decision-making processes related to health care, with mutual benefits among those involved. However, the implementation of IP services seems to differ across regions and healthcare facilities. Thus, there is a need to characterize the service provided in Brazil from the perspective of health professionals.

**Objectives:** To verify the perception of health professionals in relation to the service offered in EI.

**Methods:** The study design is cross-sectional. Health professionals who work in EI programs in Brazil (for at least 3 months) took part in the study. The online questionnaire was developed using Qualtrics software. This questionnaire consisted of multiple-choice questions about socioeconomic and demographic information, professional training, and professionals' perception of family involvement in EI and services. Descriptive analysis was performed.

**Results:** Twenty-two health professionals (female: n=20; 90.9%) participated in the study, the majority being physical therapists (n=14; 63.6%), and the others speech therapists (n=3; 13.6%), occupational therapists (n=2; 9.1%), psychologists (n=2; 9.1%), and nurse (n=1; 4.5%). Most of them work in a multidisciplinary team (n=19; 86.4%); 12 participants (54.5%) answered that they have less than 10 years of experience and nine (40.9%) that they have more than 10 years of experience in EI. Most answered that they talk about the therapeutic goals with the family (n=21; 95.5%) and that they consider the needs of the family when establishing intervention goals ("always": n=16; 72.7%; and "most of the time": n=5; 22.7%).

Regarding the involvement of family members, part of the professionals answered that most family members wait in the waiting room until the end of the session (n=8; 36.4%) during EI care; others answered that the families stay by their side observing the session (n=8; 36.4%), or effectively participate in the session (n=6; 27.3%). More than half of the professionals answered that only half of the families (n=12; 54.5%) are interested in receiving and following orientations in the home environment. Furthermore, professionals reported that they have favorable conditions to provide adequate care to children and their families (n=18; 81.8%) and that they are satisfied with their work environment (n=20; 90.9%).

**Conclusion:** From the perspective of professionals, most of them have considered the needs of families in the EI. However, they reported that not all families seem to be involved in this process.

**Implications:** Health professionals seem to consider the family-centered care approach during their EI care. However, they should explore new strategies to involve families more effectively.

**Keywords:** Family, Health professional, Early intervention

**Conflict of interest:** The authors declare no conflict of interest.

**Acknowledgment:** We thank the health professionals for collaborating by dedicating their time to answer the questionnaire.

**Ethics committee approval:** Ethics Committee of the Faculty of Ceilândia (CEP/FCE) of the University of Brasilia (UnB), with the Certificate of Presentation of Ethical Appreciation (CAAE - 63169122.0.0000.8093).

reliable data capture with minimal noise and their chromophore alteration patterns corresponded to those already observed in other voluntary muscles. There are limitations (sample size, use of spectu-

lum and unfeasibility of further statistical analyses), however, good quality data were presented with individualized and careful assess-

ment of the muscles submitted to training regardless of the
dysfunction.

Conclusion: NIRS has the potential for acquiring information not previously accessible, but it is not yet ready for clinical practice, requiring further studies to explore its potential in providing PCO,
currently not available through other means.

Implications: In PFM training, we lack standardized methodologies to quantify strength and resistance measurements, which is a chal-

lenge for clinical treatment planning. Obtaining PCO, through NIRS
technology, can improve the understanding of PFM dysfunctions and respond to the call for techniques that improve care.

ASSOCIATION BETWEEN “TEXT NECK” AND NECK PAIN IN ADULTS: A LONGITUDINAL
STUDY

Igor Macedo Tavares Correia1, Arthur de Sá Ferreira1, Jessica Fernandes1, Felipe José Jandre Reis1, Leandro Alberto Calazans Hogueira1, Ney Kiezlat-Filho1
1 Centro Universitário Augusto Motta (UNISUAM), Rio de Janeiro, Rio de Janeiro, Brasil
2 Instituto Federal do Rio de Janeiro (IFRJ), Rio de Janeiro, Rio de Janeiro, Brasil

Background: “Text neck” is defined by the cervical flexion adopted when using mobile devices. The possible causal relationship between this posture and neck pain is still widely discussed.

Objectives: The aim of this study was to investigate this association.

Methods: It is a longitudinal observational study. The sample con-
sisted of 396 volunteers without neck pain aged between 18 and 65 years. Sociodemographic, anthropometric, lifestyle (level of physical activity, smoking, sleep quality), psychosocial (anxiety, depression, social isolation) and smartphone use issues were assessed using a self-reported questionnaire. Text neck was assessed by measuring the cervical flexion angle of participants standing while typing text on their smartphones, using the cervical range of motion (CRoM) device at baseline. Two questions were used to assess the point prevalence and frequency of neck pain one year after baseline: “Did you have neck pain today?” With the following answer options “yes” or “no” and “How often do you have neck pain?”, the answer options were “very often”, “often”, “from time to
time”, “rarely” and “never”.

Results: Of the total, 84% (n=335) of participants completed the one-year follow-up. Neck pain was reported by 10% (n=40) of the sample. The average cervical flexion angle of the standing partici-
pants using the smartphone was 34° (SD=12). Multiple logistic regression analysis showed that participants’ neck flexion angle while standing using a smartphone was not associated with neck pain (OR = 1.01; 95% CI: 0.98–1.04; p=0.64) or frequency of neck pain (OR = 1.01; 95% CI: 0.99–1.03; p=0.44) one year after baseline. Of the potential confounders, sleep quality was associated with neck pain (OR = 1.76; 95% CI: 1.18–2.62; p=0.006) and frequency of
neck pain (OR = 1.53, CI 95%; 1.19–1.96; p=0.001). When compared to active participants, insufficiently active participants increased the chances of neck pain (OR = 2.42; 95%CI: 1.04–5.63; p=0.04).

Conclusion: “Text neck” was not associated with neck pain or fre-
quency of neck pain in adults.

Implications: These results challenge the belief that poor neck pos-
ture while using smartphones leads to neck pain and may help miti-
gate the impact of negative information on the cervical spine.

ANALYSIS OF ANXIETY INVENTORY SCALE
FOR RESPIRATORY DISEASES (RAI) FOR
INDIVIDUALS WITH CHRONIC OBSTRUCTIVE
PULMONARY DISEASE

Ingrid Toretti1, Sabrina Leal Pheideit1, Ana Clara Jablonksi Lampè1, Marieli Ferrarezi Alexandre1, Suelen Cristina Lehmann Schmitz1, Danielle Soares Rocha Vieira1
1 Federal University of Santa Catarina, Campus Araranguá, Santa
Catarina, Brazil

Background: Anxiety is a frequent comorbidity in patients with
Chronic Obstructive Pulmonary Disease (COPD) and with important repercussions, such as functional impairment, decreased quality of
life and adherence to treatment, and increased risk of hospitaliza-
tion. In this context, the Anxiety Inventory for Respiratory Diseases
(AIR), the only instrument specifically developed to investigate anxiety symptoms in this population, was cross-culturally adapted for use in Brazil. Still, the measurement properties of the face-to-face
version have not yet been investigated.

Objectives: To investigate the internal consistency, test-retest and
inter-rater reliability, convergent and divergent validity of the face-
to-face AIR in patients with COPD.

Methods: This is a cross-sectional methodological study. On the first
day, after signing the Free and Informed Consent Form, the Mini-
Mental State Examination, the sociodemographic and clinical ques-
tionnaire were applied, and anthropometric data were collected, followed by spirometry. Subsequently, patients answered the Modi-
fied Medical Research Council (mMRC), the COPD Assessment Test
(CAT), the AIR, the Hospital Anxiety and Depression Scale (HADS),
the Beck Anxiety Inventory (BAI), and the London Chest Activity of
Daily Living (LCADL). To determine the test-retest and inter-rater
reliability of the IAR, seven days after the first application of the
questionnaire, the leading researcher reapplied the scale with a
control form via telephone contact, and a second rater contacted
patients 48 hours later. The internal consistency of the AIR was mea-
sured using Cronbach’s alpha and reliability using the intraclass Cor-
relation Coefficient (ICC). Spearman’s correlation test (rho) was
used to determine validity (p<0.05).

Results: Twelve individuals (7 female, age 60.5 (min. 53.7-
max.70.8) years) participated in the study; nine were included in the
test-retest reliability analyses and eight in the inter-rater reli-
ability. For internal consistency, Cronbach’s α was 0.94. For test-
retest reliability, the ICC was 0.73; for inter-rater reliability, it was
0.88. Regarding convergent validity, significant correlations of high
magnitude were observed between the AIR and the HADS anxiety
domain (rho = 0.82), depression domain (rho = 0.87), and the total
score (rho = 0.79), and of moderate magnitude between the AIR and
the BAI (rho = 0.70). For divergent validity, non-significant
